Unité de Catalyse et Chimie du Solide

Equipe Verres et RMN

Université de Lille

- Verres de phosphates ?
- Applications des verres et vitrocéramiques de phosphates : bibliographie (et contributions de l'UCCE)
 - Verres pour l'optique
 - Verres de confinement de déchets nucléaires
 - Verres pour applications biologiques

- P [Ne] 3s² 3p³ => hybridation sp³
- P⁵⁺, Si⁴⁺, B³⁺
- Coordination tétraédrique : présence d'électrons π
- P=O d=0,145nm, P-O-P d=0,15 à 0,16 nm
- Délocalisation des électrons π
- Conséquence structurale :
 - silicates : Q⁰ à Q⁴, phosphates Q⁰ à Q³
 - P⁵⁺ très peu compatible avec Si⁴⁺, mais très compatible avec Al³⁺ ou B³⁺
 => Verres de phosphates « à réseaux mixtes »

Groupe isolé:
Q⁰

Phosphate glasses: compositions

Silicate glasses

Invert silicate glasses

Phosphate glasses

Mixed network phosphate glasses
(Alumino-, Boro-, Vanado-, ...)

- Q^0 à Q^3 => Réseau moins polymérisé que silicates
- Liaisons P-O-M labiles
 - => Tg basse
 - Valeur typique 300 à 400°C
 - => Coefficients de dilatation élevés (10 à $25 \cdot 10^{-6} K^{-1}$)
 - => faible durabilité chimique

- Conséquence chimique : z/a^2 très élevé, donc oxyde très acide
 - P : $2,16 \cdot 10^{20} \text{ m}^{-2}$
 - Si: $1,54 \cdot 10^{20} \text{ m}^{-2}$
 - B: $1,39 \cdot 10^{20} \text{ m}^{-2}$
 - $\text{P}_2\text{O}_5 + \text{O}^{2-} \leftrightarrow 2\text{PO}_3^-$
 - Très fort pouvoir dissociant (perles de fluoX)
 - Accepte quasiment tous les oxydes, en grande quantité : zones de vitrifications très étendues (verres à réseaux mixtes)
 - Verres « réducteurs » (cas du Cr uniquement en Cr^{3+})

Verres à réseau mixte: aluminophosphates

Laser glasses

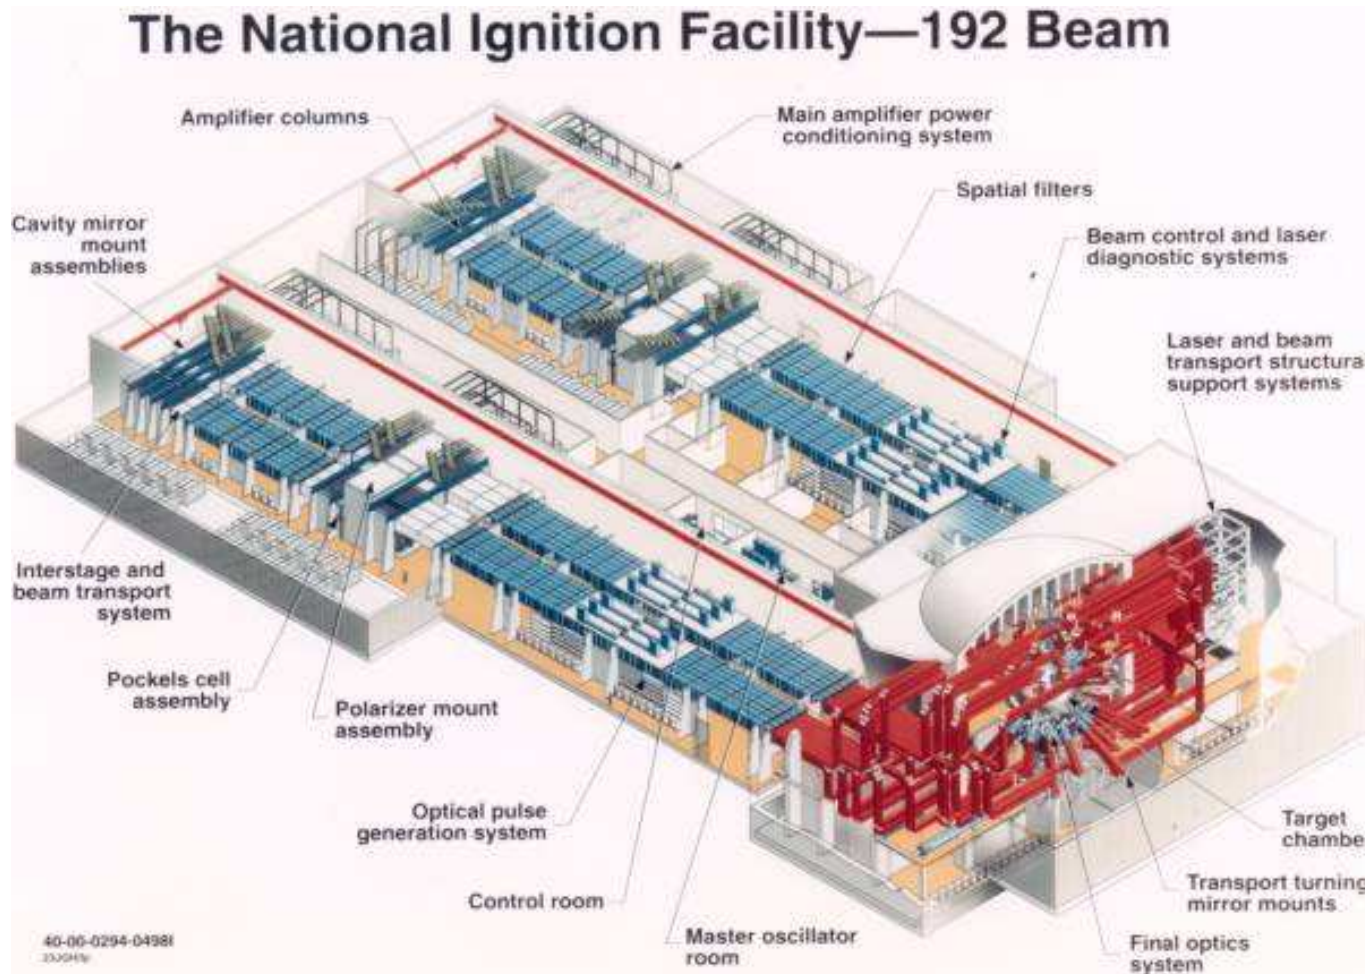

Waste storage

Anti-oxidation coating

Development of continuous melting of phosphate laser glass

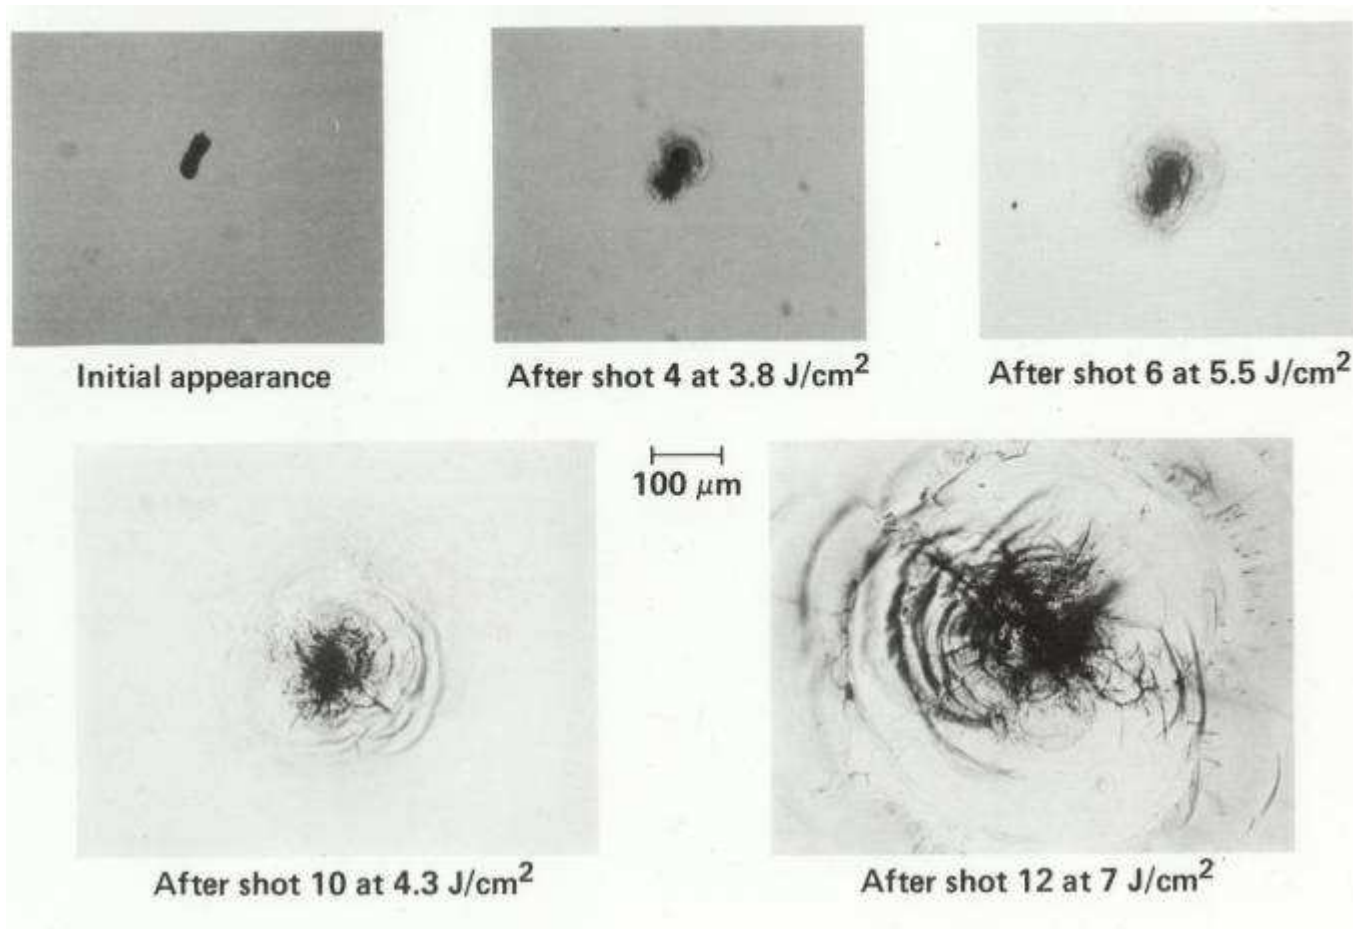

Artist Rendition of National Ignition Facility (NIF) Laser

- The NIF laser alone required 3000 slabs (150 metric ton) with the following specifications:
 - Index uniformity to $<\pm 0.000001$
 - Free of inclusions and bubbles larger than 100 μm
 - Residual hydroxyl content $<100\text{ppmw}$
 - Platinum particle free
 - Free of all detectable striae
 - Low 1054nm absorption of $<.19\%$ per cm thickness

Beamlet eighteen liter rare earth doped phosphate glass amplifier slab

Damage grows with successive shots above the damage threshold

- Redeposited platinum vapor of spatial size $>0.3\mu\text{m}$ can damage on the next shot
- Below $0.3\mu\text{m}$, the heat is conducted into the glass
- Laser glass parts became unusable after only a few high power shots

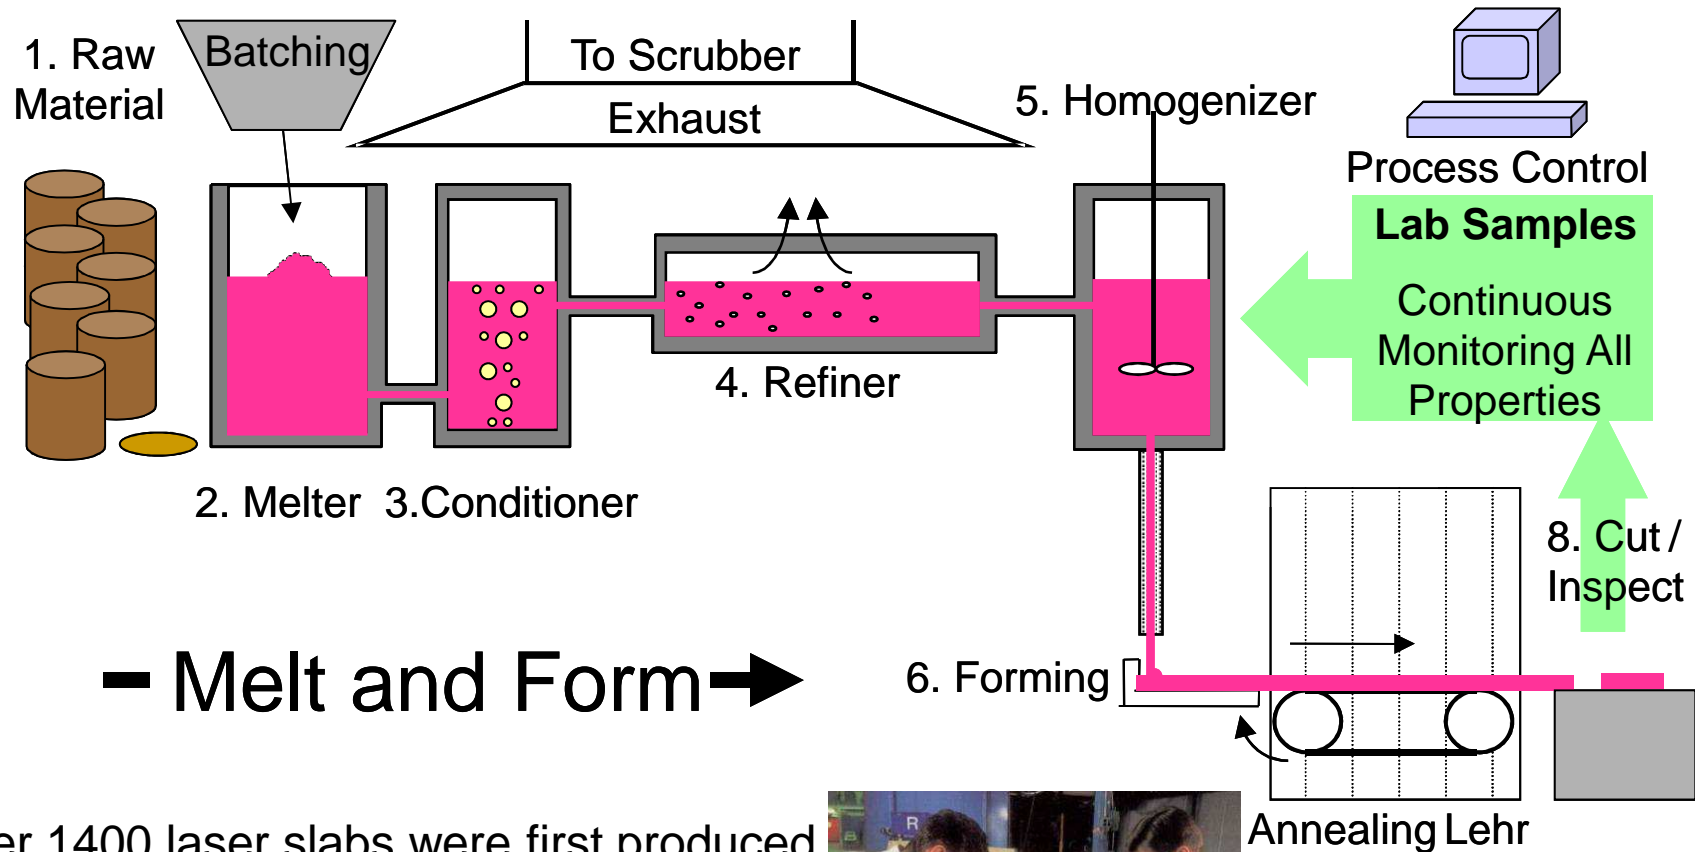

The key to solving the Pt particle problem was to dissolve the particles into the glass structure as ionic Pt^{4+}

- Dissolve inclusions under oxidizing conditions ($Pt + n/4 O_2 \rightleftharpoons Pt^{n+} + n/2 O^{2-}$)
- Minimize thermal gradients to reduce vapor transport $Pt^0 + O_2 \rightleftharpoons PtO_2 (g)$

- Platinum particles appear to be created at the start of the melt cycle
- Dissolution is limited by diffusion of platinum away from the particle surface
- Care must be taken to avoid the late arrival of Pt particles into the melt from condensed vapors

Meeting the laser glass requirements in terms of cost, quality, and rate of delivery for NIF

- Melt and Form →

Over 1400 laser slabs were first produced by the new continuous melting process

$x \geq 30$

$Q^1 + Q^0, NbO_6$ clusters

Phosphate glasses and nuclear waste vitrification

Phosphate glasses and nuclear waste vitrification

- Alternative solution to borosilicate glasses for special wastes
 - High load
 - Larger solubility of chromium, molybdenum
 - Lower melting T : less volatilization of sulfur, iodine
- 70' : USSR: Mamoshin: aluminophosphate glasses
- 80': USA: Sales and Boatner : Pb-Fe phosphate glasses
- 90': USA: Day : Fe phosphate glasses

- 1) Low melting T : $\sim 900-1100$ °C;
- 2) High waste loading;
- 3) Chemically durable P-O-Fe bonds in glass structure.

iron phosphate glass

C.-W. Kim, D.E. Day JNCS (2010)

- Contains 26 wt% of the Hanford AZ-102 LAW
 - Targets high sulfate (4.3 wt%) and high Na₂O (20 wt%)
 - Approximately 3x greater waste loading than typical borosilicate
- Recommended processing temperature of 1000 - 1050°C
- High retention of Cs, Re, and SO₃ in laboratory melts
- Meets PCT and VHT durability requirements for Hanford L disposal (regardless of thermal history)
- Melt viscosity and electrical conductivity within acceptable for JHM and CCIM processing
- Compatible with Inconel 693/690 and K-3 refractory

Open questions:

Chemical durability (long term)

Devitrification resistance

Corrosiveness

Simulated waste glass cylinder, 8 liters, melted at 1200°C (Brow, personal communication)

Immobilization of Radioactive iodine in phosphate glasses

Why Iodine?

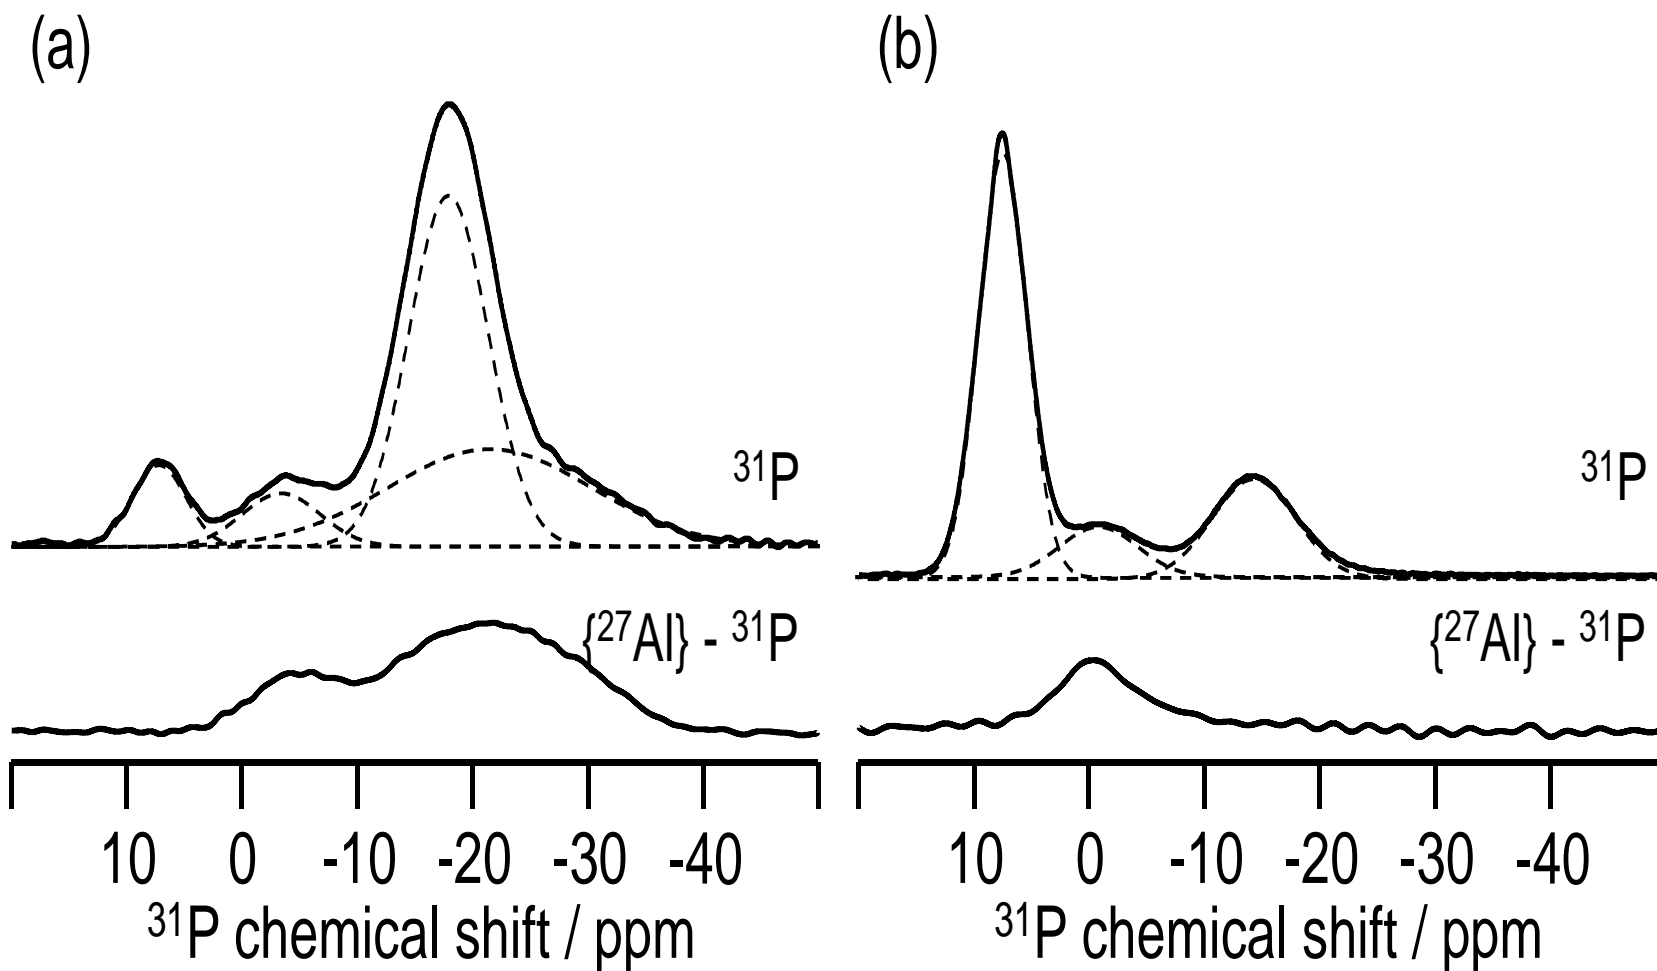

- ❑ ^{129}I : radioactive isotope extracted during the processing of the nuclear fuel
- ❑ **MAVL's waste** (Medium activity waste with a long life).
 - ❑ High mobility in the geologic environment
 - ❑ Strong tendency to volatilization (600°C)

- Silver phosphate glasses
 - ❑ Low melting T
 - ❑ High incorporation rate for I

Influence of the incorporation of AgI on the structure as a function of Ag/P by ^{31}P NMR

Addition of AgI for different ratios of Ag/P changes the chemical shift: modification of angles and bond length in phosphate network

Using the business - Leveraging Innovation

"To stop glasses becoming cloudy in the dishwasher, add glass."

Photo: The McGraw-Hill Companies

Hard water in dishwashers can cause limescale build-up on glasses. This can be removed with salt and rinse-aid. Soft water can cause glass corrosion. This can't be removed but at least it can now be prevented.

© 2011 The McGraw-Hill Companies

Apart from water softness, glass corrosion depends on the glass, the temperature and cleanliness of the water, the length of the cycle and the type of dirt. Preventing further corrosion depends on us.

Photo: The McGraw-Hill Companies

Our R&D people fight glass corrosion with glass. They've developed a special glass with a higher percentage of silica. This silicate glass dissolves in the wash-water and prevents further corrosion. We can't replace it in washers with top covers. (Industry complaint). Anyway, the silicate glass slowly dissolves over about 30 cycles, protecting glasses from corrosion.

Refusing to let this go, we set this new problem at Calgonit's R&D center in its main laboratory, allowing water to flow through tubes to the test. As the glass dissolves, it deposits itself on the glasses in the dishwasher, stopping them from being scratched or corroded. It works by softening the water, dissolving limescale out of the water so they can't cause corrosion. Clear stuff, in fact, it's so clear we've patented the use of the mineral for this purpose.

Our tests showed that the product has no negative effect on glass, dishes or people. It works by softening the water so that it can't cause corrosion. Clear stuff, in fact, it's so clear we've patented the use of the mineral for this purpose.

Our tests showed that the product has no negative effect on glass, dishes or people. It works by softening the water so that it can't cause corrosion. Clear stuff, in fact, it's so clear we've patented the use of the mineral for this purpose.

The new production received a thumbs-up from retailers. As a genuine innovation, it's essential to protect your investment without affecting much shelf space. In fact, we've been used Calgonit® products in Central Europe, using a full commercial test to improve the performance of glass corrosion and the solution is simple. Your solution has been great, making that every cloudy glass has a shining.
